Introduction 2

Key Findings 2

Analysis 4

Artefact Table 4

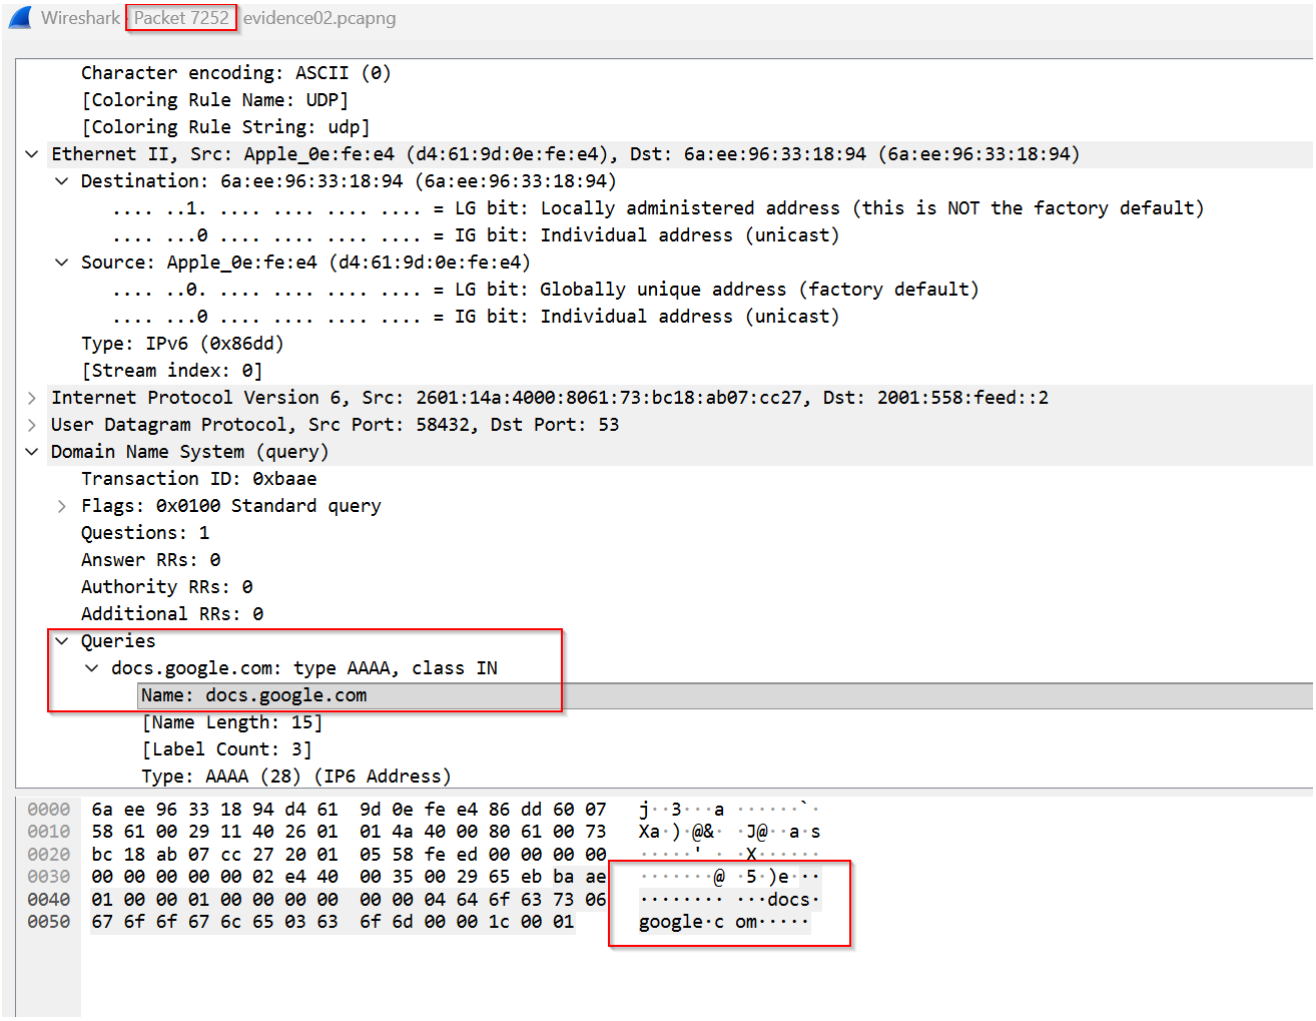

Introduction

This document provides an overview and analysis of file ‘evidence02.pcapng’, a packet capture containing a total of 7442 packets. The capture majorly consists of data from internal host 10.0.0.210 containing large amounts of high-volume traffic. Much of the heavy traffic is directed to port ‘65206’.

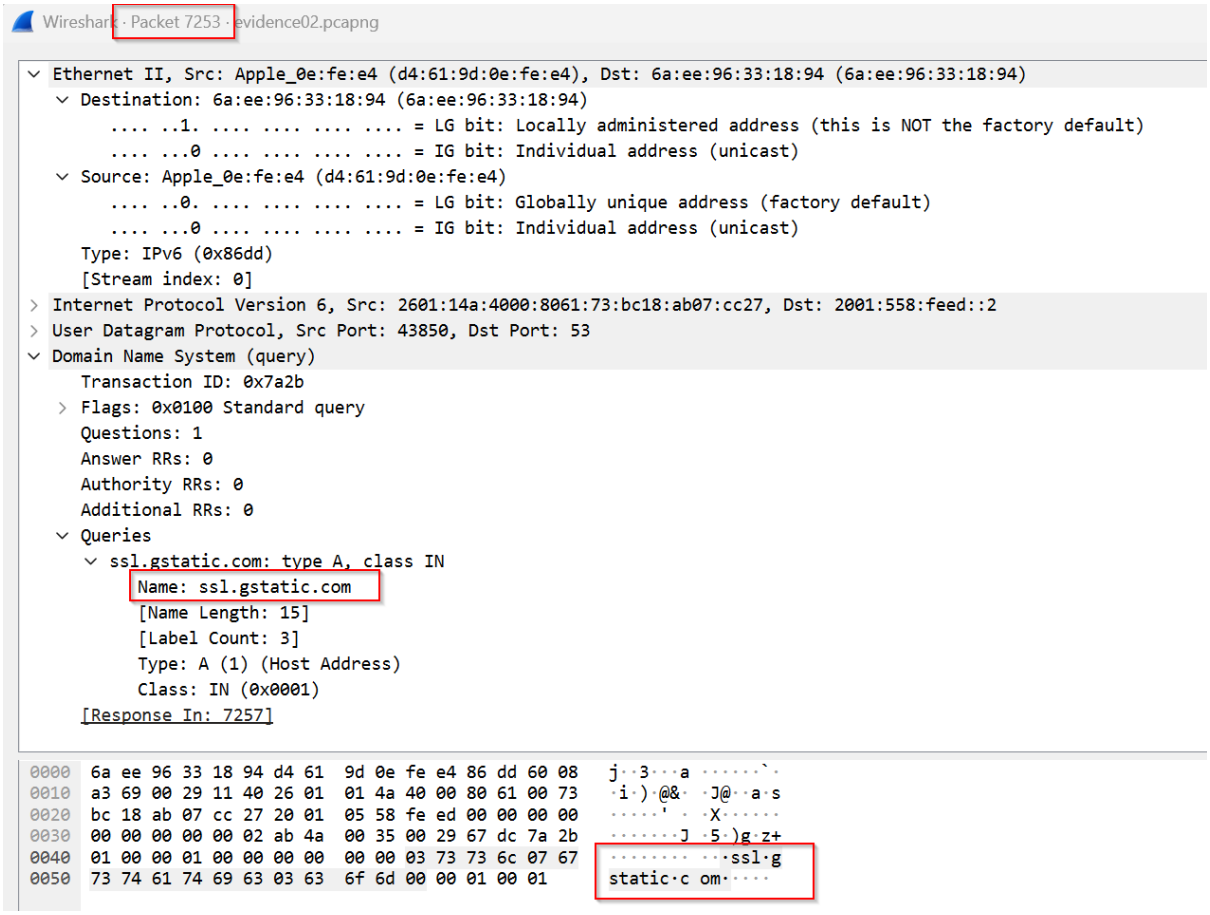

Key Findings

A majority of the traffic contained within this packet capture contains large amounts of data and is going between internal host 10.0.0.210 and IP address 17.132.29.71. Packets appear to be using port 443 which indicates why the data cannot be read as this port is used for HTTPS – the secure encrypted version of HTTP traffic.

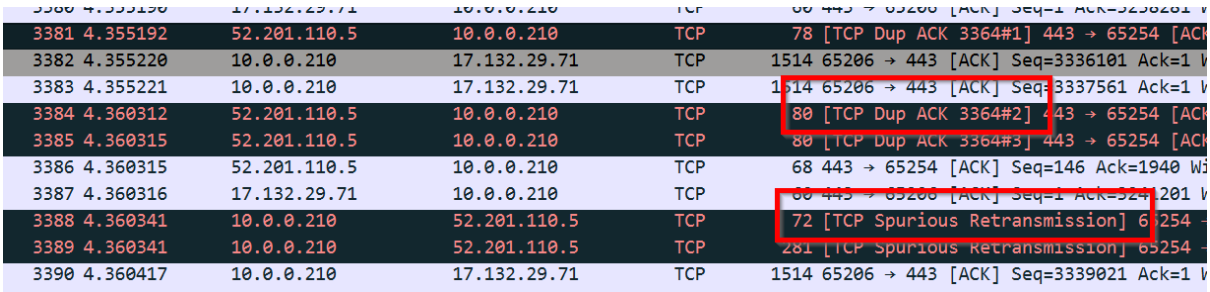

Under frame 7252, a link to google docs can be found which is evidence of interaction with this website. This effect is not exclusive to this frame; it can be found in a handful of frames.

In frame 7253, there is interaction with 'ssl.gstatic.com' which is found in a handful of packets, similar to the activity found with frames containing the address to google docs.

From packets 3381 to 3403, 7202 to 7210 and 7346 to 7349, there are signs of a temporary loss of network stability as packet's read with "TCP Dup ACK flags" and "TCP Spurious Retransmission."

Analysis

The primary concern is the large amount of data being transmitted between 10.0.0.210 and 12.132.29.71 partially because the port used is ‘ephemeral’. No solid conclusion can be made as all transmitted data is encrypted.

Artefact Table

Artefacts	**Location**	**Type of Artefacts**	**Contents / Reason behind Compromise**
